

Researchers cause use this information to see as technology has advanced and become more popular, we are subject to more breaches. In the database timeline it can also reflect on what was going on in the world during that time when the breaches occurred. Majority of the breaches are due to hacks, what is concerning based off of this database that a lot of breaches are in the unknown category. For me that is concerning that the most common breach has not been established by other categories. Based off of the map as well, different states are more effected than others. States like California, Texas and Florida have higher instances. Smaller density states or areas like the mid-west have lower instances.
