

Social cybersecurity is all about how technology is changing the way people behave and how societies work. It's becoming really important for national security because it can affect how wars are fought, both online and offline. For example, countries can use information to influence what people think and to divide societies, making them weaker without using traditional weapons.

This field combines different sciences, like sociology and psychology, to understand and predict how people will act online. It's not just about hacking computers, it's about influencing and hacking people's minds. This can include things like spreading fake news, manipulating social media, and creating division in societies. One big worry is information warfare, where countries use information as a weapon to weaken their enemies. Russia, for example, has been accused of using information to create conflict and division in other countries.
